

### 363.1 GlusterFS Storage Clusters (weight: 5)

**Weight** 5

**Description** Candidates should be able to manage and maintain a GlusterFS storage cluster.

**Key Knowledge Areas:**

- Understand the architecture and components of GlusterFS
- Manage GlusterFS peers, trusted storage pools, bricks and volumes
- Mount and use an existing GlusterFS
- Configure high availability aspects of GlusterFS
- Scale up a GlusterFS cluster
- Replace failed bricks
- Recover GlusterFS from a physical media failure
- Restore and verify the integrity of a GlusterFS cluster after an outage
- Awareness of GNFS (Ganesha NFS)

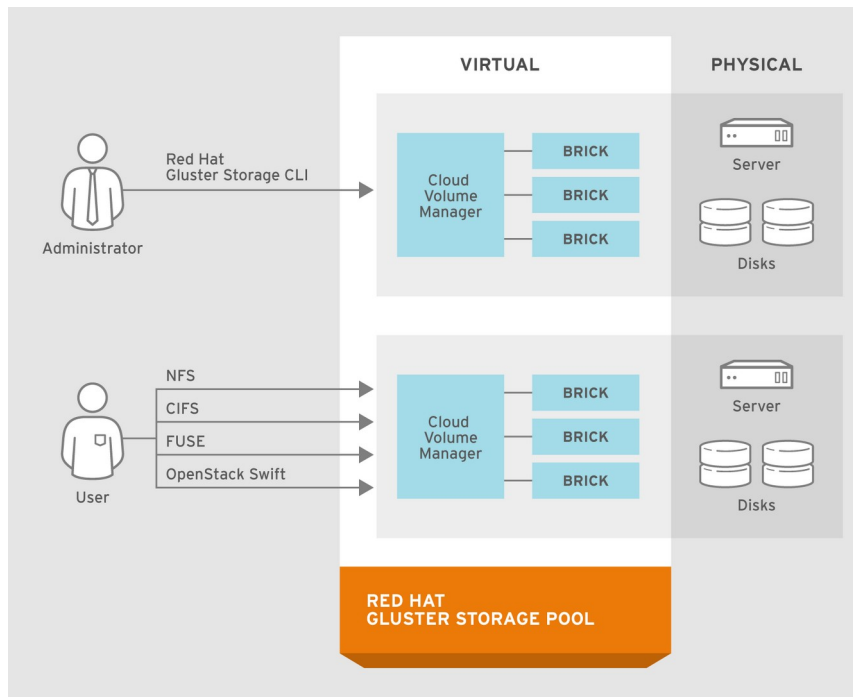

**Partial list of the used files, terms and utilities:**

- gluster (including relevant subcommands)

→ → [Conceptos Preliminares.](#)

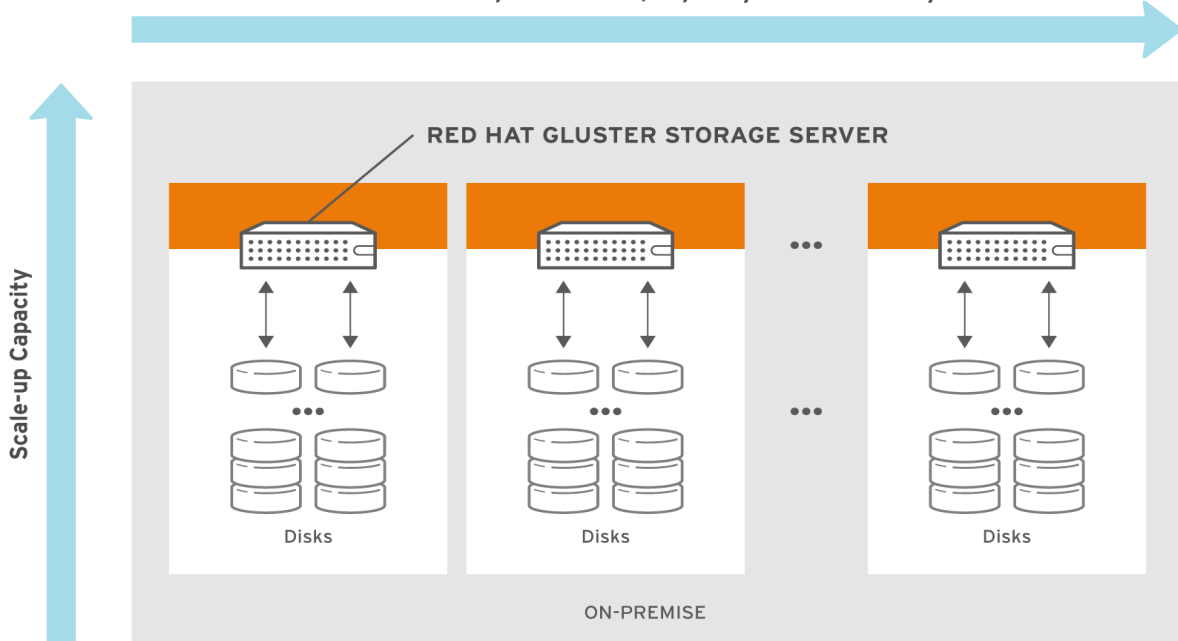

#### **Arquitectura GlusterFS.**

En el núcleo del diseño de Red Hat Gluster Storage se encuentra un método completamente nuevo de diseñar la arquitectura del almacenamiento. El resultado es un sistema que tiene una inmensa escalabilidad, es altamente resistente y ofrece extraordinarias actuaciones. En un sistema de escalamiento horizontal, uno de los mayores desafíos es realizar un seguimiento de las ubicaciones lógicas y físicas de datos y metadatos. La mayoría de los sistemas distribuidos resuelven este problema creando un servidor de metadatos para rastrear la ubicación de datos y metadatos. A medida que los sistemas tradicionales agregan más archivos, más servidores o más discos, el servidor central de metadatos se convierte en un cuello de botella de rendimiento, así como un punto central de falla. A diferencia de otras soluciones de almacenamiento tradicionales, Red Hat Gluster Storage no necesita un servidor de metadatos, y localiza archivos algorítmicamente usando un algoritmo de hash elástico. Esta arquitectura de servidor sin metadatos asegura un mejor rendimiento, escalabilidad lineal y confiabilidad.

#153460\_GLUSTER\_1.0\_334434\_0415

Scale-out performance, capacity and availability

#145075\_GLUSTER\_1.0\_334434\_0415

### Conceptos de Almacenamiento.

#### → **Brick**

The glusterFS basic unit of storage, represented by an export directory on a server in the trusted storage pool. A brick is expressed by combining a server with an export directory in the following format:

SERVER:EXPORT

#### → **Volume**

A volume is a logical collection of bricks. Most of the Red Hat Gluster Storage management operations happen on the volume.

#### → **Translator**

A translator connects to one or more subvolumes, does something with them, and offers a subvolume connection.

#### → **Subvolume**

A brick after being processed by at least one translator.

#### → **Volfile**

Volume (vol) files are configuration files that determine the behavior of your Red Hat Gluster Storage trusted storage pool. At a high level, GlusterFS has three entities, that is, **Server**, **Client** and **Management daemon**. Each of these entities have their own volume files. Volume files for servers and clients are generated by the management daemon upon creation of a volume.

Server and Client Vol files are located in `/var/lib/glusterd/vols/VOLNAME` directory.

The management daemon vol file is named as **glusterd.vol** and is located in `/etc/glusterfs/` directory.

#### → **glusterd**

glusterd is the glusterFS Management Service that must run on all servers in the trusted storage pool.

#### → **Cluster**

A trusted pool of linked computers working together, resembling a single computing resource. In Red Hat Gluster Storage, a cluster is also referred to as a trusted storage pool.

#### → **Client**

The machine that mounts a volume (this may also be a server).

→ **File System**

A method of storing and organizing computer files. A file system organizes files into a database for the storage, manipulation, and retrieval by the computer's operating system.

→ **Distributed File System**

A file system that allows multiple clients to concurrently access data which is spread across servers/bricks in a trusted storage pool. Data sharing among multiple locations is fundamental to all distributed file systems.

→ **Virtual File System (VFS)**

VFS is a kernel software layer that handles all system calls related to the standard Linux file system. It provides a common interface to several kinds of file systems.

→ **POSIX**

Portable Operating System Interface (for Unix) (POSIX) is the name of a family of related standards

specified by the IEEE to define the application programming interface (API), as well as shell and utilities interfaces, for software that is compatible with variants of the UNIX operating system. Red Hat Gluster Storage exports a fully POSIX compatible file system.

→ **Metadata**

Metadata is data providing information about other pieces of data.

→ **FUSE**

Filesystem in User space (FUSE) is a loadable kernel module for Unix-like operating systems that lets non-privileged users create their own file systems without editing kernel code. This is achieved by running file system code in user space while the FUSE module provides only a "bridge" to the kernel interfaces.

→ **Geo-Replication**

Geo-replication provides a continuous, asynchronous, and incremental replication service from one site to another over Local Area Networks (LAN), Wide Area Networks (WAN), and the Internet.

→ **N-way Replication**

Local synchronous data replication that is typically deployed across campus or Amazon Web Services Availability Zones.

**→ Petabyte**

A petabyte is a unit of information equal to one quadrillion bytes, or 1000 terabytes. The unit symbol for the petabyte is PB. The prefix peta- (P) indicates a power of 1000:

$$1 \text{ PB} = 1,000,000,000,000,000 \text{ B} = 1000^5 \text{ B} = 10^{15} \text{ B}.$$

The term "pebibyte" (PiB), using a binary prefix, is used for the corresponding power of 1024.

**→ RAID**

Redundant Array of Independent Disks (RAID) is a technology that provides increased storage reliability through redundancy. It combines multiple low-cost, less-reliable disk drives components into a logical unit where all drives in the array are interdependent.

**→ RRDNS**

Round Robin Domain Name Service (RRDNS) is a method to distribute load across application servers. RRDNS is implemented by creating multiple records with the same name and different IP addresses in the zone file of a DNS server.

**→ Server**

The machine (virtual or bare metal) that hosts the file system in which data is stored.

**→ Block Storage**

Block special files, or block devices, correspond to devices through which the system moves data in the form of blocks. These device nodes often represent addressable devices such as hard disks, CD-ROM drives, or memory regions. As of Red Hat Gluster Storage 3.4 and later, block storage supports only OpenShift Container Storage converged and independent mode use cases. Block storage can be created and configured for this use case by using the gluster-block command line tool. For more information, see Container-Native Storage for OpenShift Container Platform.

**→ Scale-Up Storage**

Increases the capacity of the storage device in a single dimension. For example, adding additional disk capacity in a trusted storage pool.

**→ Scale-Out Storage**

Increases the capability of a storage device in single dimension. For example, adding more systems of the same size, or adding servers to a trusted storage pool that increases CPU, disk capacity, and throughput for the trusted storage pool.

**→ Trusted Storage Pool**

A storage pool is a trusted network of storage servers. When you start the first server, the storage pool consists of only that server.

**→ Namespace**

An abstract container or environment that is created to hold a logical grouping of unique identifiers or symbols. Each Red Hat Gluster Storage trusted storage pool exposes a single namespace as a POSIX mount point which contains every file in the trusted storage pool.

**→ User Space**

Applications running in user space do not directly interact with hardware, instead using the kernel to moderate access. User space applications are generally more portable than applications in kernel space. glusterFS is a user space application.

**→ Hashed subvolume**

A Distributed Hash Table Translator subvolume to which the file or directory name is hashed to.

**→ Cached subvolume**

A Distributed Hash Table Translator subvolume where the file content is actually present. For directories, the concept of cached-subvolume is not relevant. It is loosely used to mean subvolumes which are not hashed-subvolume.

**→ Linkto-file**

For a newly created file, the hashed and cached subvolumes are the same. When directory entry operations like rename (which can change the name and hence hashed subvolume of the file) are performed on the file, instead of moving the entire data in the file to a new hashed subvolume, a file is created with the same name on the newly hashed subvolume. The purpose of this file is only to act as a pointer to the node where the data is present. In the extended attributes of this file, the name of the cached subvolume is stored. This file on the newly hashed-subvolume is called a linkto-file. The linkto file is relevant only for non-directory entities.

**→ Directory Layout**

The directory layout helps determine where files in a gluster volume are stored.

When a client creates or requests a file, the DHT translator hashes the file's path to create an integer. Each directory in a gluster subvolume holds files that have integers in a specific range, so the hash

of any given file maps to a specific subvolume in the gluster volume. The directory layout determines which integer ranges are assigned to a given directory across all subvolumes.

Directory layouts are assigned when a directory is first created, and can be reassigned by running a rebalance operation on the volume. If a brick or subvolume is offline when a directory is created, it will not be part of the layout until after a rebalance is run. You should rebalance a volume to recalculate its directory layout after bricks are added to the volume.

#### → **Fix Layout**

A command that is executed during the rebalance process.

The **rebalance** process itself comprises of two stages:

1. Fixes the layouts of directories to accommodate any subvolumes that are added or removed. It also heals the directories, checks whether the layout is non-contiguous, and persists the layout in extended attributes, if needed. It also ensures that the directories have the same attributes across all the subvolumes.
2. Migrates the data from the cached-subvolume to the hashed-subvolume.

#### → **Topología**

##### # cat /etc/hosts

```
127.0.0.1 localhost localhost.localdomain localhost4 localhost4.localdomain4
```

```
::1 localhost localhost.localdomain localhost6 localhost6.localdomain6
```

##### ## Servers glusterFS.

```
192.168.10.161 gluster01.cadilinea.lan gluster01
```

```
192.168.10.162 gluster02.cadilinea.lan gluster02
```

```
192.168.10.163 gluster03.cadilinea.lan gluster03
```

##### # lsblk /dev/vd[b-z]

```
NAME MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
```

```
vdb 252:16 0 20G 0 disk
```

```
vdc 252:32 0 20G 0 disk
```

```
vdd 252:48 0 20G 0 disk
```

#### → **Sincronización Horaria.**

Todos los hosts deben estar sincronizados previamente → NTP chronyc por ejemplo.

```
# systemctl status chronyd.service
```

→ Instalación.

En todos los nodos:

```
# dnf install glusterfs-server -y
```

```
# systemctl enable --now glusterd
```

→ bash-completion para gluster

```
cd /etc/bash_completion.d/
```

```
./gluster
```

(Es necesario reiniciar el Sistema).

```
# gluster --version
```

```
glusterfs 8.4
```

```

**gluster01 ~ # gluster volume remove-brick repVol-01 replica 2**

**gluster03:/bricks/repVol-01/data start**

Replica 2 volumes are prone to split-brain. Use Arbiter or Replica 3 to avoid this. See:  
<http://docs.gluster.org/en/latest/Administrator%20Guide/Split%20brain%20and%20ways%20to%20deal%20with%20it/>.

Do you still want to continue?

(y/n) y

It is recommended that remove-brick be run with cluster.force-migration option disabled to prevent possible data corruption. Doing so will ensure that files that receive writes during migration will not be migrated and will need to be manually copied after the remove-brick commit operation. Please check the value of the option and update accordingly.

Do you want to continue with your current cluster.force-migration settings? (y/n) y

volume remove-brick start: failed: Migration of data is not needed when reducing replica count. Use the 'force' option

**gluster01 ~ # gluster volume remove-brick repVol-01 replica 2**

**gluster03:/bricks/repVol-01/data force**

Remove-brick force will not migrate files from the removed bricks, so they will no longer be available on the volume.
